

DCN704 – Collaborative Communications Laboratory Report

Lab # 5 (5%): VoIP protocols

Student Name: **Fatjon Dauti**

Student ID #: **151413192**

Total marks: 5

Learning outcomes

- To identify the protocols needed for Collaboration Services
- To analyze the protocol operations when different VoIP services run across the network
- To compare protocols and architectures in terms of quality of service

Part 1. SIP

Open the following capture files using Wireshark and perform the indicated steps:

[SIP-RTP on G.711](#)

[SIP-RTP on G.729](#)

I have appended my name to the .pcap files for the screenshots, so that it will show in each window title below.

1. **[0.25 marks]** Display the complete Protocol Hierarchy for each capture file.

Insert the screenshot of these windows here.

2. **[0.25 marks]** What are the Transport Layer and Application Layer protocols involved in these captures?

The transport layer protocol involved is UDP, the application layer protocols are RTP and SIP

3. **[0.25 marks]** Identify the SIP flows in each capture. How many different SIP conversations are included in these captures?

Insert the screenshot of these windows here.

2 conversations in the first capture (g711), 1 in the second capture (g729a)

Wireshark · SIP Flows · sip-rtp-g711-fatjondauti.pcap

| Start Time | Stop Time | Initial Speaker | From | To | Protocol | Duration | Packets | State | Comments |
|------------|-----------|-----------------|---------------------------------------|--------------------------------|----------|----------|---------|-----------|------------|
| 0.000000 | 8.504283 | 10.0.2.20 | "PCMU/8000" <sip:sipp@10.0.2.20:5060> | test <sip:test@10.0.2.15:5060> | SIP | 00:00:08 | 6 | COMPLETED | INVITE 200 |
| 8.619801 | 8.624534 | 10.0.2.20 | "PCMA/8000" <sip:sipp@10.0.2.20:5060> | test <sip:test@10.0.2.15:5060> | SIP | 00:00:00 | 4 | IN CALL | INVITE 200 |

Wireshark · SIP Flows · sip-rtp-g729a-fatjondauti.pcap

| Start Time | Stop Time | Initial Speaker | From | To | Protocol | Duration | Packets | State | Comments |
|------------|-----------|-----------------|---------------------------------------|--------------------------------|----------|----------|---------|-----------|------------|
| 0.000000 | 8.506934 | 10.0.2.20 | "G729/8000" <sip:sipp@10.0.2.20:5060> | test <sip:test@10.0.2.15:5060> | SIP | 00:00:08 | 6 | COMPLETED | INVITE 200 |

4. **[0.25 marks]** Play and compare the SIP streams. How can you compare them? How similar or different are they?

Regarding SIP, we can apply “sip” in Wireshark as a filter, to filter only SIP related traffic. From Telephony window - SIP Flows, I can check the flow sequence for each SIP stream. They are similar in terms that there is a sequence that follows each call, for instance first packet is a SIP INVITE packet which initiates the telephone call. We see default SIP port 5060 UDP being used. For the first g711 file, I can see that the second SIP stream was interrupted without the BYE method to end the SIP session properly, so the call might have been disconnected. Also I noticed that some SIP Requests have a protocol of SIP/SDP in the Protocol column and by searching online it is the Session Description Protocol which is used for session invitation and parameter negotiation.

5. **[0.25 marks]** What stream offers the best quality? How do you measure the quality of a SIP-RTP stream?

Insert the screenshot of these windows showing the time graph of the streams here.

The see statistics that helps us determine the quality of SIP-RTP streams I used the RTP Stream Analysis in Wireshark.

Wireshark · RTP Stream Analysis · sip-rtp-g711-fatjondauti.pcap

As we can see by comparing the rtp stream from each codec, with G729a we incur more Jitter (variation in packet delays), and this can be problematic for voice calls. As expected, G729a which uses compression, requires much less bandwidth as we see in the RTP stream above.

6. [0.25 marks] Display the call flow sequence of each call.

Insert the screenshot of these windows here.

7. [0.25 marks] Describe a typical SIP call sequence. How does it start? How does it finish?

As seen in the flow sequences above, a SIP call sequence starts with an INVITE request sent by the caller phone. The other SIP phone responds with Trying, meaning that it is attempting the connection. When the other phone responds with SIP Status 200 OK, the call has been answered. The caller phone acknowledges the successful invite with INVITE ACK. Voice packets will start to be transmitted through RTP. In the sequence above we can see RTP flow direction and the codec being used. When the other phone hangs up, a BYE request is sent to the caller phone. The caller phone confirms the end of the session with a SIP Status 200 OK.

8. [0.25 marks] What advice can be given to an end user, if you have to recommend one particular compression algorithm?

When deciding what codec to use I would balance between the quality of voice calls desired and bandwidth available on WAN links. If bandwidth is not a problem I would recommend the user to use a codec that does little compression, this way the quality of voice calls would be superior.

In case the user or business, needs to make a high number of calls at the same time while sacrificing quality without it being noticeable on voice conversations a codec that provide more compression can be used.

Part 2. H.248

Open the following Packet Tracer capture and perform the following steps:

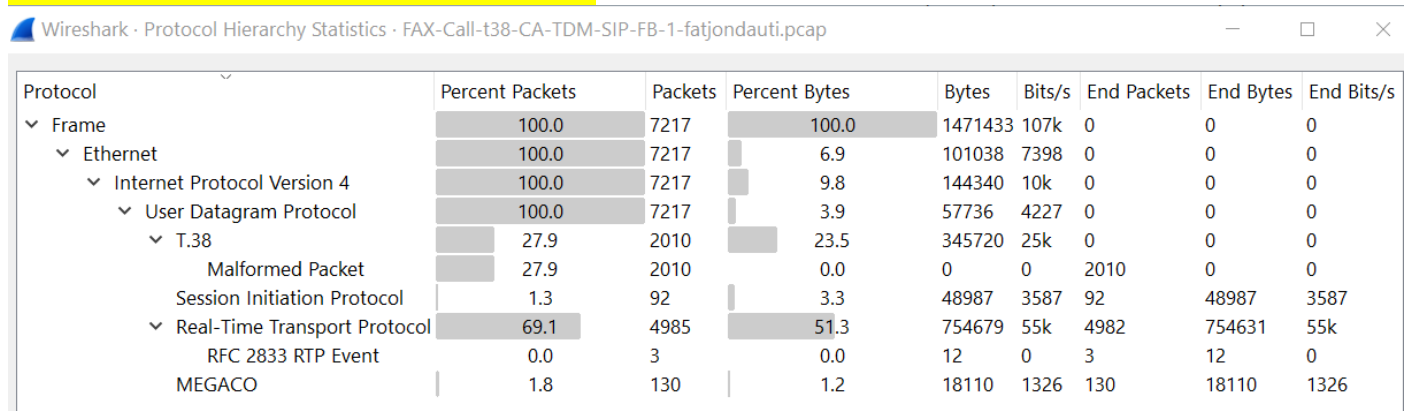

[Fax call from TDM to SIP over Mediagateway with declined T38 request, megaco H.248.](#)

1. [0.25 marks] What end-user service is this capture about?

This capture is about sending Fax data over IP network.

2. [0.25 marks] Display the complete Protocol Hierarchy on each capture file.

Insert the screenshot of these windows here.

Wireshark · Protocol Hierarchy Statistics · FAX-Call-t38-CA-TDM-SIP-FB-1-fatjondauti.pcap

6. [0.25 marks] Other than the OK status (check mark symbol), what are the other statuses of the packets in the same stream?

Other status are "Payload changed", "Wrong sequence number", "Incorrect timestamp", "Comfort noise".

7. [0.5 marks] Study the RFC3389 standard. How can you apply this standard in VoIP services?

The RFC 3389 standard, defines a standard for distributing comfort noise information in VoIP systems. Real-time Transport Protocol (RTP) is the protocol used for transporting comfort noise (CN). CN is used with audio codecs that do not support comfort noise as part of the codec itself such as G.711 in this example. This standard is applied in VoIP services to avoid prolong periods of total silence, which might make the listener think that the transmission has been lost and hang up prematurely. CN will fill those silent portions of transmissions with artificial noise.

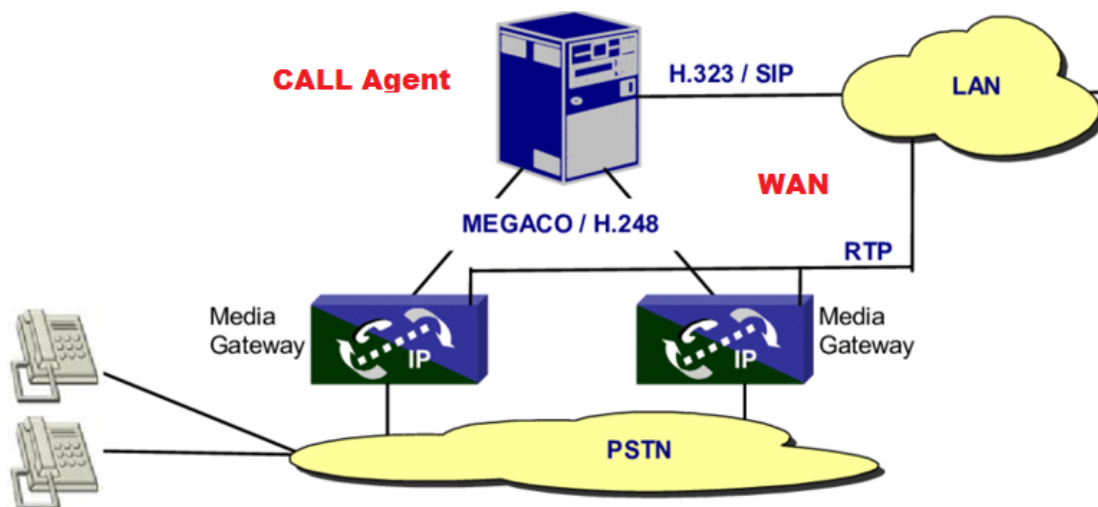

Part 3. Conclusion

1. **[0.5 marks]** Make a comparison between SIP and H.248. In which cases do you use one or the other? Or Both?

As defined in the Soft-switch architecture big picture, H.248 would be used to provide gateway-to-gateway (Media Gateway to Media Gateway Controller or Call Agent) interface for SIP (signaling between call agents or call processors). SIP and Megaco used together allows fax, video, and data to flow from PSTN to IP networks and back to PSTN.

2. **[0.5 marks]** Illustrate your answer with a network example, including a diagram of the network in each case.

The image I found below offers a good example of illustrating the answer above, in a scenario that includes both MEGACO-H248 and SIP.
